

The baseline model worked reasonably well on the original dataset, but it made more mistakes when tested on my own gesture style, especially on some of the digits that looked different from the training examples. After fine-tuning on my collected data, the model became more consistent and the confidence scores improved for most gestures. Overall, the fine-tuned model performed better because it adapted to my personal drawing patterns instead of relying only on the pretrained data. Although I do think that some human error could be accounted for because it is hard to consistently draw the numbers accurately using the Arduino Nano 33 BLE.
